Key Lesson learned:

- **Value of careful phenotyping**
- **Evaluation as iterative process**
- **Expect new/very rare conditions, variant presentations**
- **Advance care, advance knowledge**

Purpose: This report describes the National Institutes of Health Undiagnosed Diseases Program, details the Program's application of genomic technology to establish diagnoses, and details the Program's success rate during its first 2 years.

Methods: Each accepted study participant was extensively phenotyped. A subset of participants and selected family members (29 patients and 78 unaffected family members) was subjected to an integrated set of genomic analyses including high-density single-nucleotide polymorphism arrays and whole exome or genome analysis.

Results: Of 1,191 medical records reviewed, 326 patients were accepted and 160 were admitted directly to the National Institutes of Health Clinical Center on the Undiagnosed Diseases Program service. Of those, 47% were children, 55% were females, and 53% had neurologic disorders. Diagnoses were reached on 39 participants (24%) on clinical, biochemical, pathologic, or molecular grounds; 21 diagnoses involved rare or ultra-rare diseases. Three disorders were diagnosed based on single-nucleotide polymorphism array analysis and three others using whole exome sequencing and filtering of variants. Two new disorders were discovered. Analysis of the single-nucleotide polymorphism array study cohort revealed that large stretches of homozygosity were more common in affected participants relative to controls.

Conclusion: The National Institutes of Health Undiagnosed Diseases Program addresses an unmet need, i.e., the diagnosis of patients with complex, multisystem disorders. It may serve as a model for the clinical application of emerging genomic technologies and is providing insights into the characteristics of diseases that remain undiagnosed after extensive clinical workup.

Genet Med 2012:14(1):51–59

Key Words: neurological disorders; rare disease; SNP arrays; undiagnosed disease; whole exome sequencing

Understanding what is important: begin from the end

Parents

Care Coordinators

Physicians, Attendings

Valued Outcomes

Coordination

- Plan and deliver efficient path to diagnosis and care
- Avoid duplications, leverage synergies, be timely
- Have a single point of contact with program

Communication

- Integrated medical Information: families, providers
- Visual, clear summary for family and PCP

Team, Process & Tools

Diagnosis

- low throughput with high demand: screen
- Review and respond to all: accept or refer

Discovery and Training

- Aligned with clinical mission
- Opportunity for next generation of clinicians & scientists

Process (simplified)

Assess, Plan, See

Team evaluation

- Referral: engage and get data
- Review: discuss and score
- Decide: accept vs. refer
- Design evaluation plan: clinical team, testing, HPO & gene lists, prelim tests (SNP array)
- See Family, finalize testing

agnostic data and gaps:

- Exome: one diagnostic finding = a single PRPS1 (OMIM 311850) missense mutation
  - on X chromosome, also present in mother (who compensated with her second copy)
- **Single gene testing: FSHD allele contraction (haplotype unknown), modifying role unclear**
- **Expansion repeats**: not done, but not needed given diagnosis
- **Mitochondrial genome**: not done, not needed given diagnosis
- **Genomic imbalances**: normal microarray
- **Environmental exposures**: significant regression after febrile episode, a possible contributor

PRPS1 Mutations:
Four Distinct Syndromes and Potential Treatment

Arjan P.M. de Brouwer,[1,*] Hans van Bokhoven,[1,2] Sander B. Nabuurs,[3] Willem Frans Arts,[4] John Christodoulou,[5,6] and John Duley[7,8]

Figure 2. Simplified Overview of the Purine Metabolism Pathway

The scheme is derived from KEGG Pathways hsa00230 (purine metabolism) and hsa00240 (pyrimidine metabolism).[12] Indicated in red is the alternative pathway to replenish purine nucleotides via SAM. Enzymes central in this review are highlighted by blue boxes. PRS-I is printed in bold. Boxes show the essential role of PRPP in the purine metabolism. Dashed arrows indicate multiple intermediate steps that are not shown. PRPP is also used for the de novo synthesis of pyrimidines, as indicated by the arrow to UMP, the central intermediate in pyrimidine pathway. In addition, PRPP is essential for pyridine nucleotide (NAD/NADP) synthesis

Parental update (Dec 2017)

- **started walking with walker, per mom vision is improving, much happier kid "quality of life increased 100%"**

Comprehensive Care Update
- objective assessment vs. baseline

SAM supplementation in the diet may alleviate some of the symptoms of the patients with *PRPS1* loss-of-function mutations by replenishing purine nucleotides independent of PRPP production. An open-label clinical trial in the two affected Australian brothers is currently under way and appears to have improved the health of the patients, although it is too early to draw significant conclusions. Patients with DFN2 and CMTX5 and mildly affected carrier females from the original Arts syndrome may also benefit from SAM supplementation in their diet.

FTP - 12 year old boy

Report date: 9 May 2016

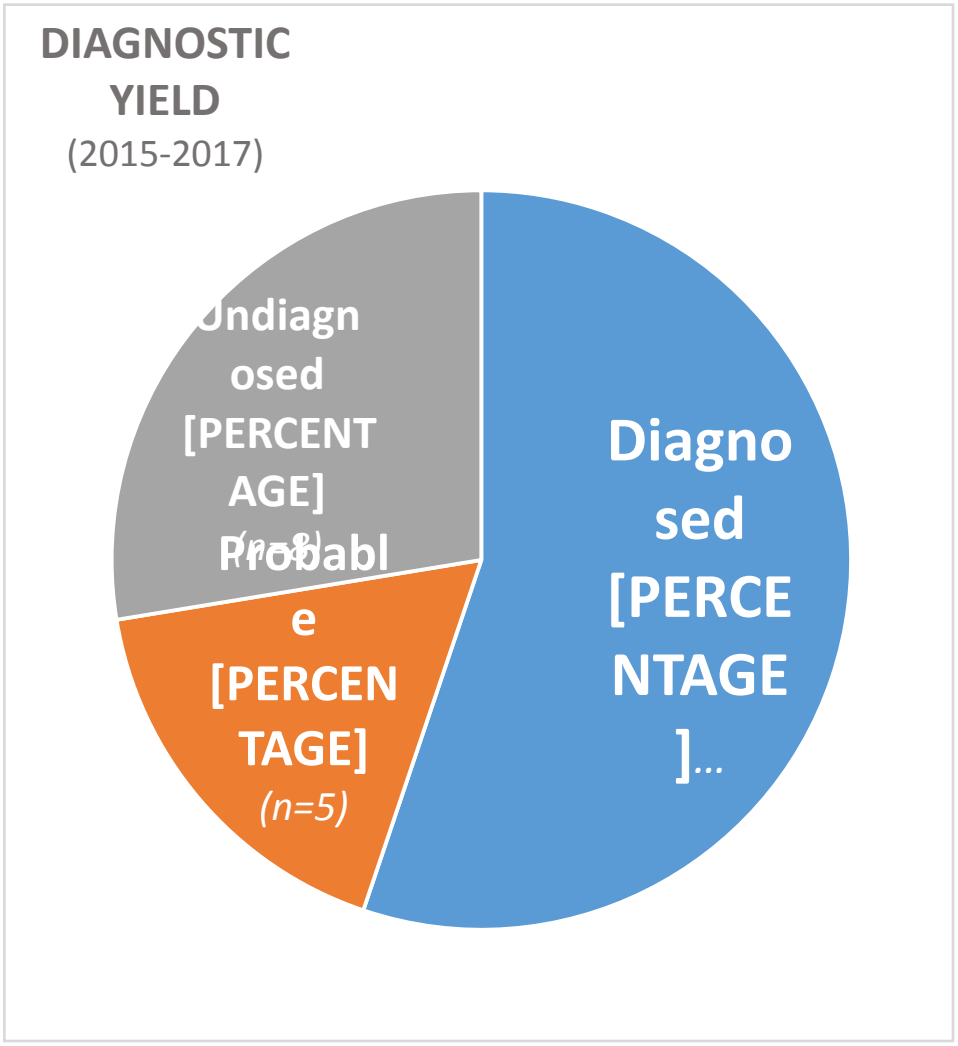
Diagnostic Odyssey: 7 years, now over

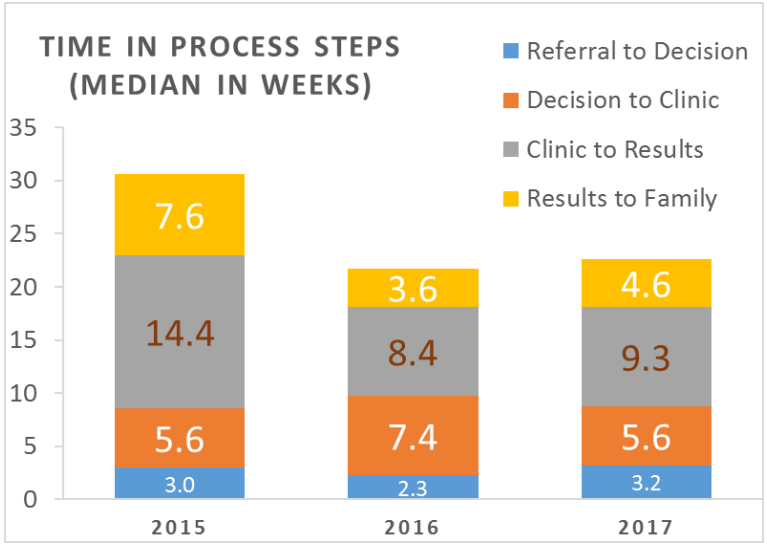
Value provided by Penelope Program

- **End of diagnostic odyssey:** **PRPS1 mutation (c.334G>C, p.V112L), associated with X-linked Charcot-Marie-Tooth disease-5 (CMTX5; OMIM 311070)**
- **Diagnosis-driven new treatment: identified pathway, connected with other clinicians (Australia), started supplementation with S-adenosyl methionine**
- **Actionable family information: X-linked, test mother for carrier status, can test other boys and treat early if affected (also, avoid diagnostic odyssey in sibs)**

Lesson 1: Good Processes and Teams Give Good Results

Favorable Diagnostic Yield (55 to 72%)
Improving Timeliness





Source: Penelope Program data updated 12/2017

Lesson 2: expect a high proportion of new or variant conditions

New condition
New gene

Atypical presentation

Ultra-rare diagnosis

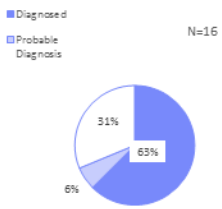
Diagnoses

- Charcot Marie Tooth type 5 (CMTX5) – Arts syndrome overlap: *PRPS1*
  - *Diagnosis-driven treatment (SAM +/- riboside), connected with other center*
- UDP Galactose transporter deficiency (CDG IIm): *SLC35A2-CDG*
  - *attempting diagnosis-driven treatment (galactose), connected to consortium*
- Progressive Osseous Heteroplasia: *GNAS*
  - *Treatment with topical thiosulfate*

- ARID1B-related intellectual disability: *avoided tumor surveillance*
- Torg-Winchester syndrome / multisystem nodular osteolysis: *MMP-2, connected to MMP-2 research (Alberta, Dr Fernandez Patron) for potential tx*

- KCND3-related early onset intellectual disability: *connected with consortium*
- HUWE1-related intellectual disability
- NONO-related syndrome (left ventricular non-compaction)
- Megalencephaly-Polymicrogyria-Polydactyly-Hydrocephalus type 3: *CCND2*
- Aicardi Goutieres type 2 (RNASEHB)

Lesson 3: clinical utility is real



Family

Family members at risk

★ Recurrence risk (de novo, Mendelian)

Management

Investigations stopped

Surveillance started stopped

New treatments ★ started

Child

Precision Diagnosis, Prognosis ★

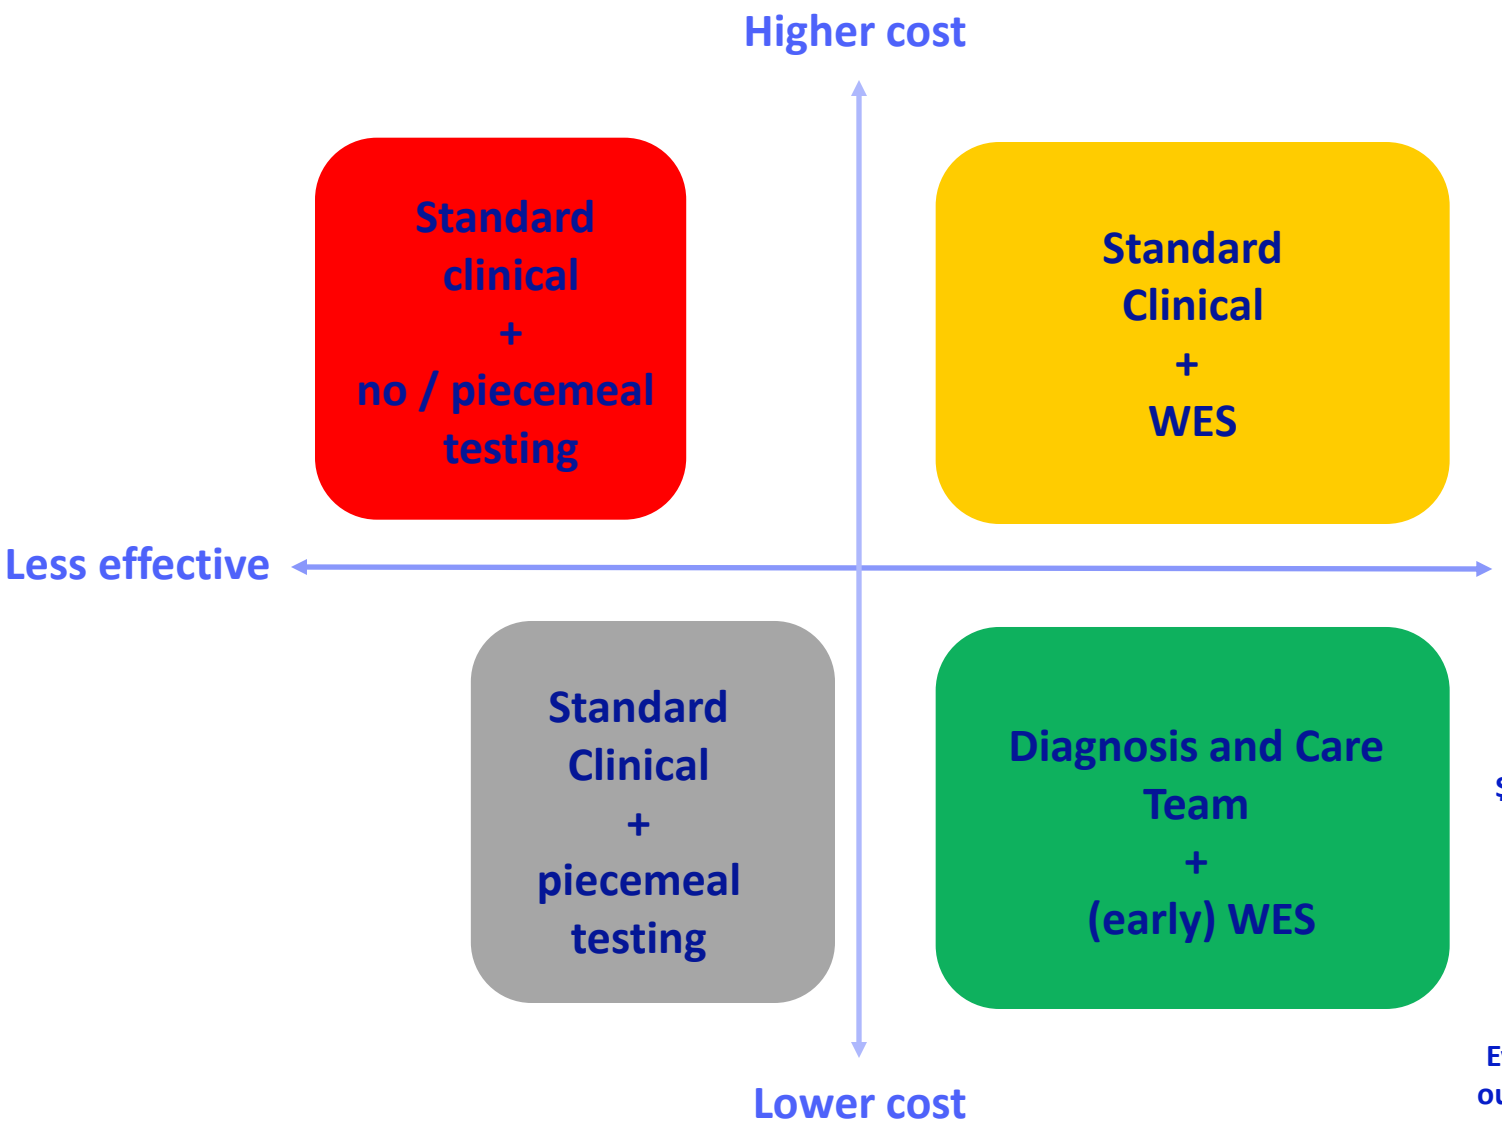
- SETD5-related intellectual disability
- STARD9-related epilepsy and developmental disability

- NOTCH1-related brain calcifications with Hirschsprung d.
- PIK3C3-related neurodevelopmental regression

- Multiple vascular hypoplasia (AR)
- Possible new osteoporosis/fractures condition: novel gene
  - connected with two other centers, working on functional studies

New vs. variant

Lesson 4: journey to better value continues



8 in-state children

Mutational Hotspot

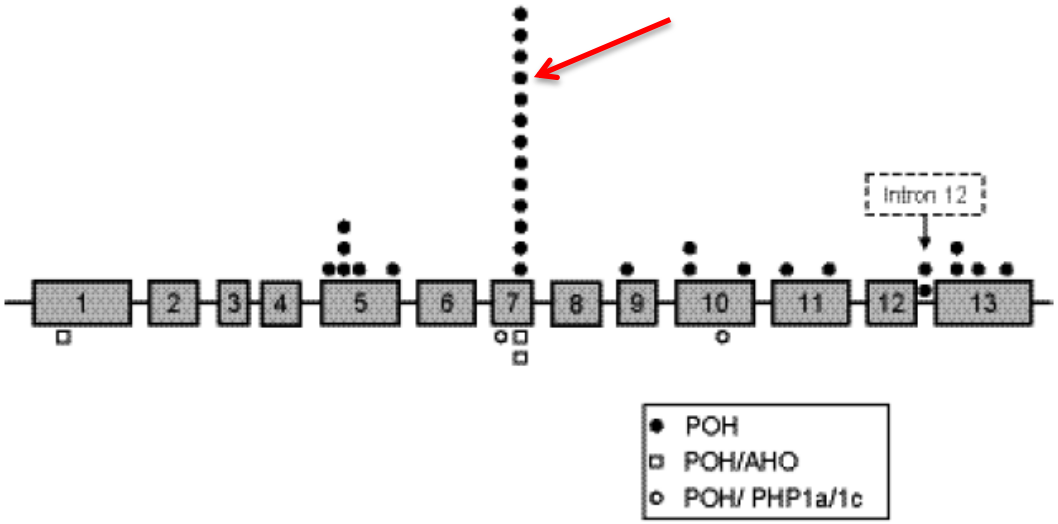

Fig. 1.
Distribution of *GNAS* mutations in POH and other conditions of progressive HO. Exons for the *GNAS* gene (Gsα mRNA) are identified by numbers and are approximately drawn to scale. Intronic sequences are represented by straight solid lines between exons. Information presented is from this study; recent reports of *GNAS* mutations in AHO and PHP1a/1c also show a wide distribution throughout the *GNAS* exons (e.g., Jan De Beur et al. [2003]; Linglart et al. [2002]; Aldred et al. [2000]). Symbols represent patients within each diagnostic group whose *GNAS* sequence analysis revealed specific mutations at the indicated approximate locations. A "hot spot" (4 base pair deletion) causing a frameshift mutation at c.565-568 occurs in exon 7.

Adegbite 2008 Am J Med Genet A

GNAS c.565_568del Reported

- This variant has been reported in patients:
  - with progressive osseous heteroplasia (**POH**) (Shore 2002, Adegbite 2008, Lebrun 2010, Schrander 2014)
  - pseudohypoparathyroidism type 1A (**PHP Ia**) (Linglart 2002, Nakamoto 1998, Yokoyama 1996, Walden 1999, Lebrun 2010, Inta 2014)
  - pseudohypoparathyroidism type 1A (PHP Ia) / pseudopseudohypoparathyroidism (PPHP) (Ahmed 1998)
  - Pseudopseudohypoparathyroidism (PPHP) (Walden 1999)
  - Albright hereditary osteodystrophy (AHO) (Weinstein 1992, Nakamoto 1998, Linglart 2002, Joseph 2011)
  - as well as in an unaffected carriers (Shore 2002, Adegbite 2008).

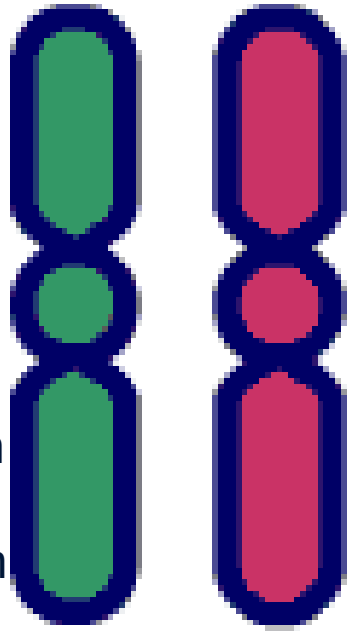
GNAS: Imprinting Gene

Paternal inactivating GNAS mutation:
Progressive osseous heteroplasia (POH) (OMIM:166350) Dominant

Phenotype:

- Onset in infancy or childhood
- Dermal ossification beginning in infancy, followed by increasing and extensive bone formation in deep muscle and fascia
- Growth retardation of limbs, short status

Paternal Maternal



Chromosome 20

Maternal GNAS mutation:
Pseudohypoparathyroidism IA (PHP Ia) (OMIM 103580) Dominant

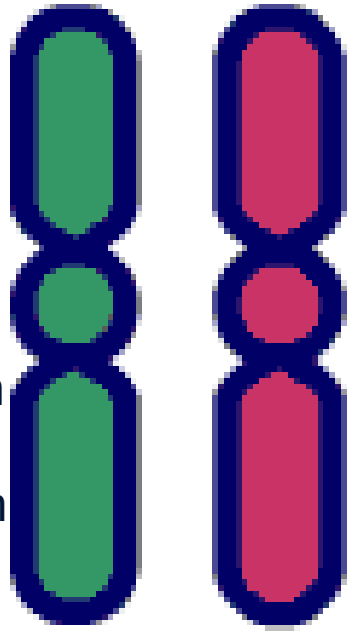
Variable phenotype:

- Resembled parathyroid hormone deficiency
- Short stature, round face, short neck, obesity, subcutaneous calcifications
- Hypocalcemia and hyperphosphatemia

Case 1: *GNAS* Paternal Mutation

Paternal inactivating GNAS mutation:
Progressive osseous heteroplasia (POH) (OMIM:166350) Dominant
Phenotype:

- Onset in infancy or childhood
- Dermal ossification beginning in infancy, followed by increasing and extensive bone formation in deep muscle and fascia
- Growth retardation of limbs, short status, scoliosis



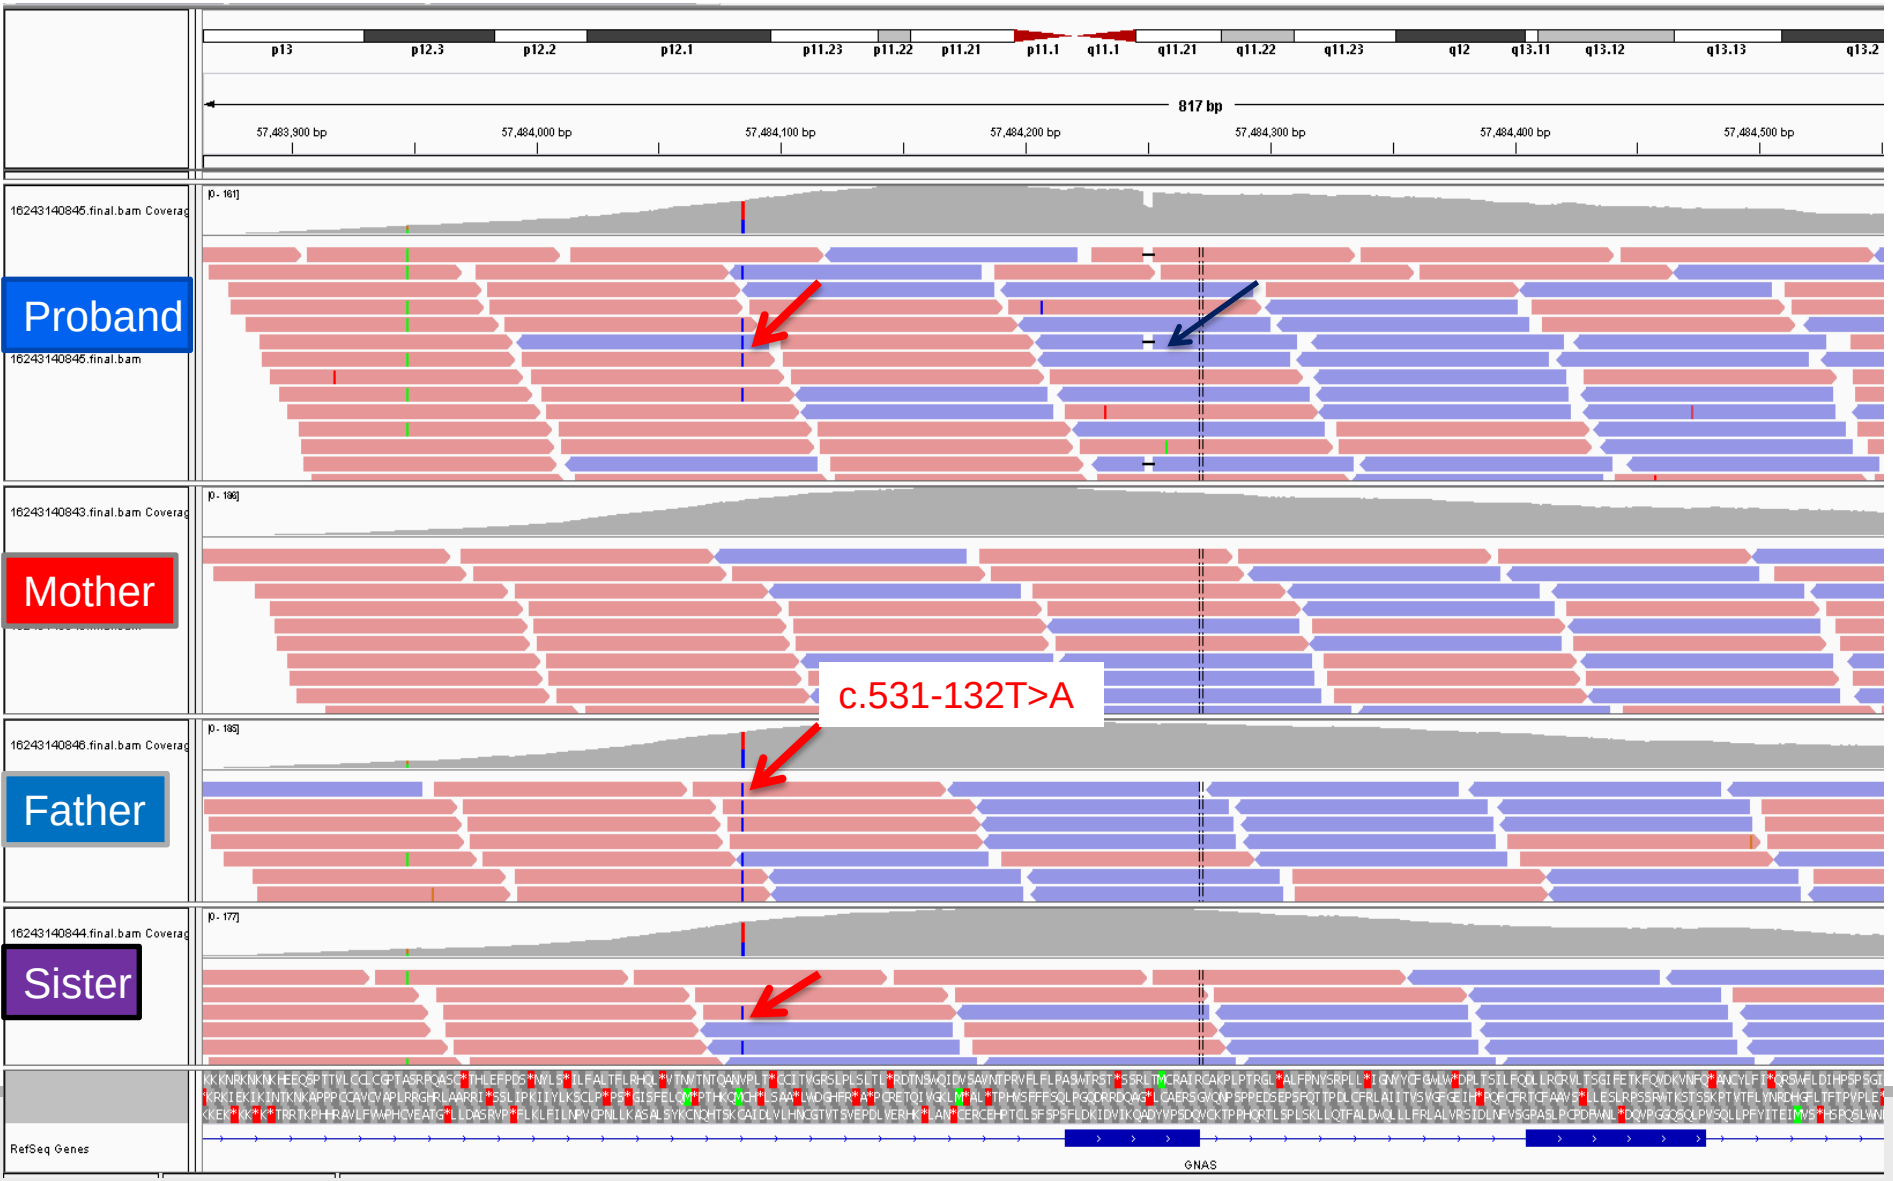
Chromosome 20

Maternal GNAS mutation:
Pseudohypoparathyroidism IA (PHP Ia) (OMIM 103580)
Dominant
Variable phenotype:

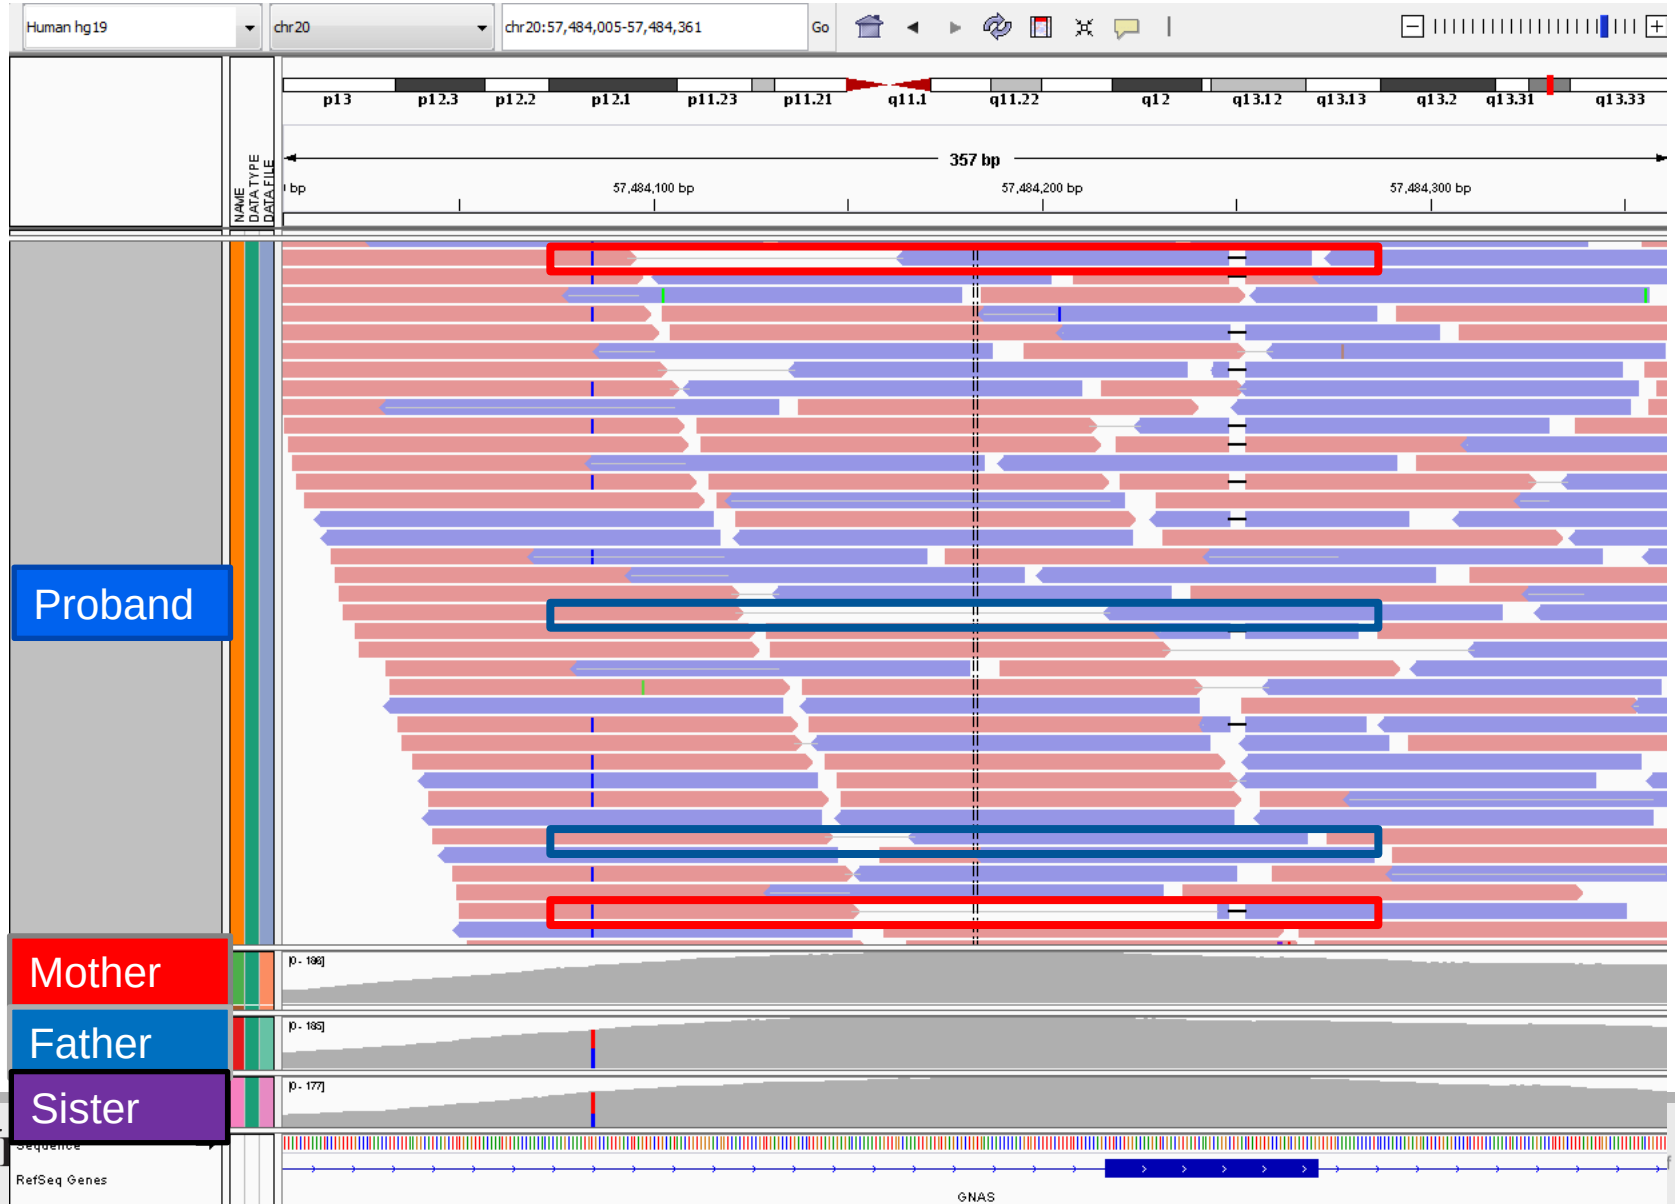
- Resembled parathyroid hormone deficiency
- Short stature, round face, short neck, obesity, subcutaneous calcifications
- Hypocalcemia and hyperphosphatemia

Case 1: *GNAS* Mutation Paternal Original?

Paternal polymorphism Chr20(GRCh37): g.57,484,085; NM_000516.4 c.531-132T>A, 170 bp away



GNAS mutation paternal original? Confirmed by Pair-end read



Case 1 *GNAS*: Paternal Inactive Mutation

- De novo c.565_568del mutation was confirmed on paternal allele.
- Consistent with dx of Progressive Osseous Heterotopia (POH)
- A very rare genetic disorder of abnormal bone formation

Therapeutic Assessment

- Physical therapy to preserve movement (unlike fibroplasia ossificans progressiva)
- Surgery not recommended
- New treatment (ongoing): topical thiosulfate (to improve solubility of Ca)
- Potential treatment: Hh inhibitors, Retinoic acid receptor γ agonists

Case 2: Unknown of Known Disease

Slides courtesy of Wei Shen, PhD

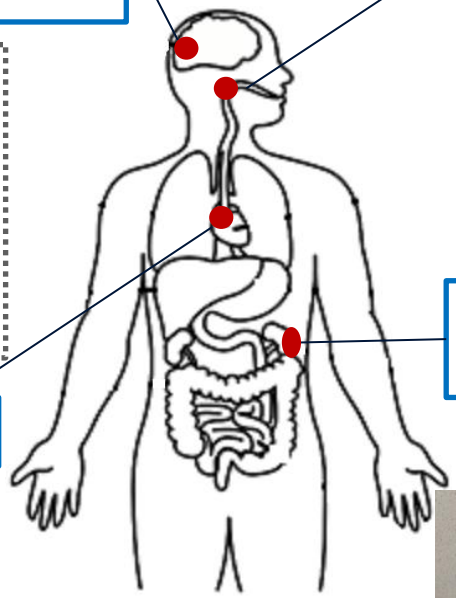
Clinical Information:

- 21-month girl

Global Developmental Delays, Hypotonia, leukoencephalopathy, brain calcifications

Dysphagia, poor feeding

Physical exam:
- Short Stature
- Dysmorphic Facial Features – Mild brachycephaly, glabellar hemangioma



Hirschsprung's Disease

Atrial septal defect

- Family history: unremarkable, healthy parents

Exome Data:

Variants (SNV)s in targeted genes: 249,851

SNVs : 3,761

Subtract common variants of frequency >1% and internal frequency 3%

SNVs: 749

Exclude intergenic, deep intronic, 5'and 3' UTRs, synonymous, and noncoding RNA

HGMD Matched Variants: 37 hits

AD: 0.1%, 0.3% ARUP: 425 hits

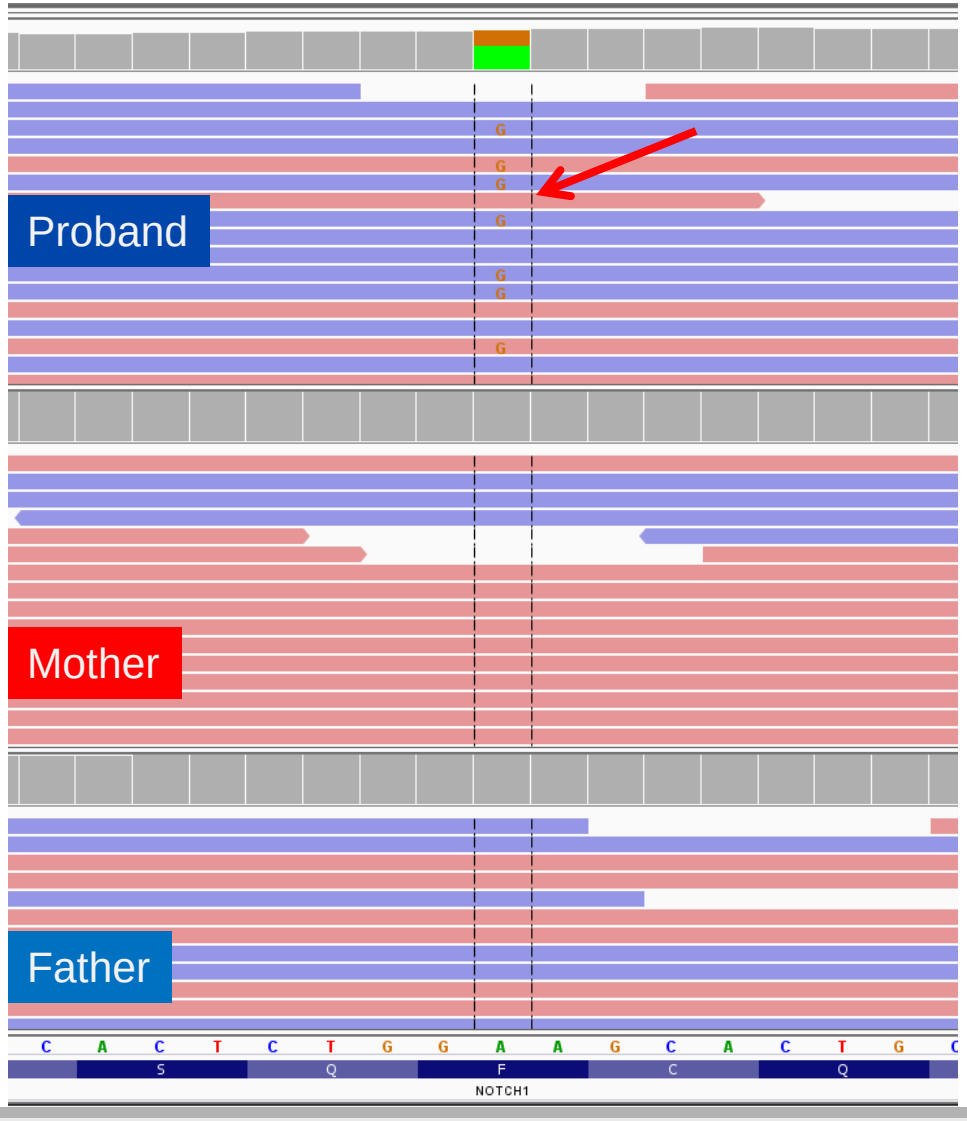
De novo: 87 hits, 1 real in IGV

NOTCH1	het	c.5078T>C	p.F1693S

AR analysis: 1% freq, 3% ARUP freq : 1 gene

NOTCH1 De Novo

Chr9(GRCh37):g.139397723 NM_017617.4 **c.5078T>C; p.Phe1693Ser**



- Very rare: not reported in ExAC, gnomAD
- Highly conserved amino acid in the HD domain
- Computational predictions (**PP3**):
  - SIFT: deleterious
  - PolyPhen-2: probably damaging
- Reported in one patient with acute leukemia (presumably somatic) (PMID 18281529)
- Variant of uncertain significance

NOTCH1 Mutations

- Adams-Oliver syndrome (MIM: 616028), autosomal dominant (loss-of-function mutations)
  - Aplasia cutis congenita of the scalp (80%)
  - Terminal transverse limb defect (85%)
  - Cutis marmorata telangiectatica congenita (20%)
  - Cardiovascular malformations/dysfunction (23%): left-sided obstructive lesions, septal defects, conotruncal defects
  - Brain anomalies (uncommon): microcephaly, cortical dysplasia, polymicrogyria, pachygyria, dysgenetic corpus callosum, cortical atrophy with ventriculomegaly, cerebral hemorrhage, intracranial calcifications, delayed myelination
  - *NOTCH1, DOCK6, DLL4, EOGT, RBPJ* and *ARHGAP31*
- Aortic valve disease (MIM: 109730), autosomal dominant
  - Bicuspid aortic valve

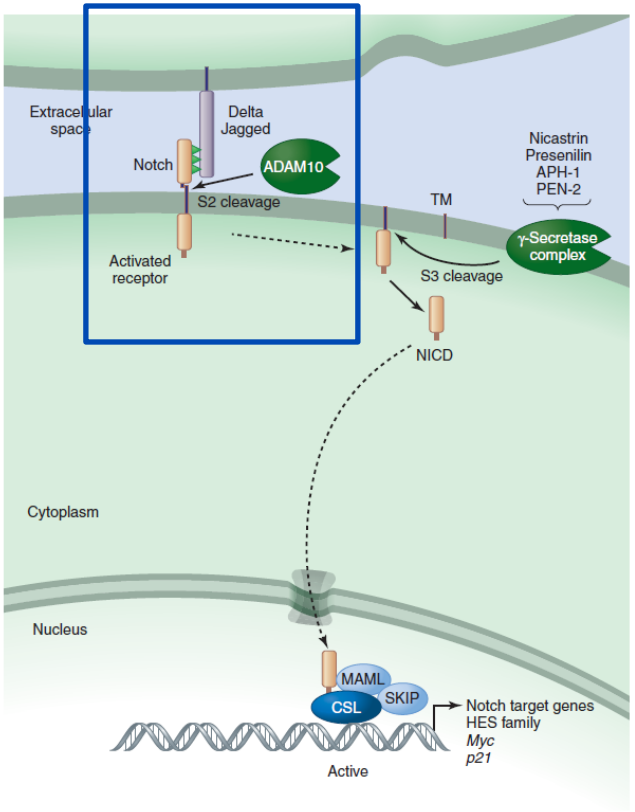


Figure 1. Notch signaling (simplified view).

Notch protein is transmembrane receptors which regulate cell decision during development

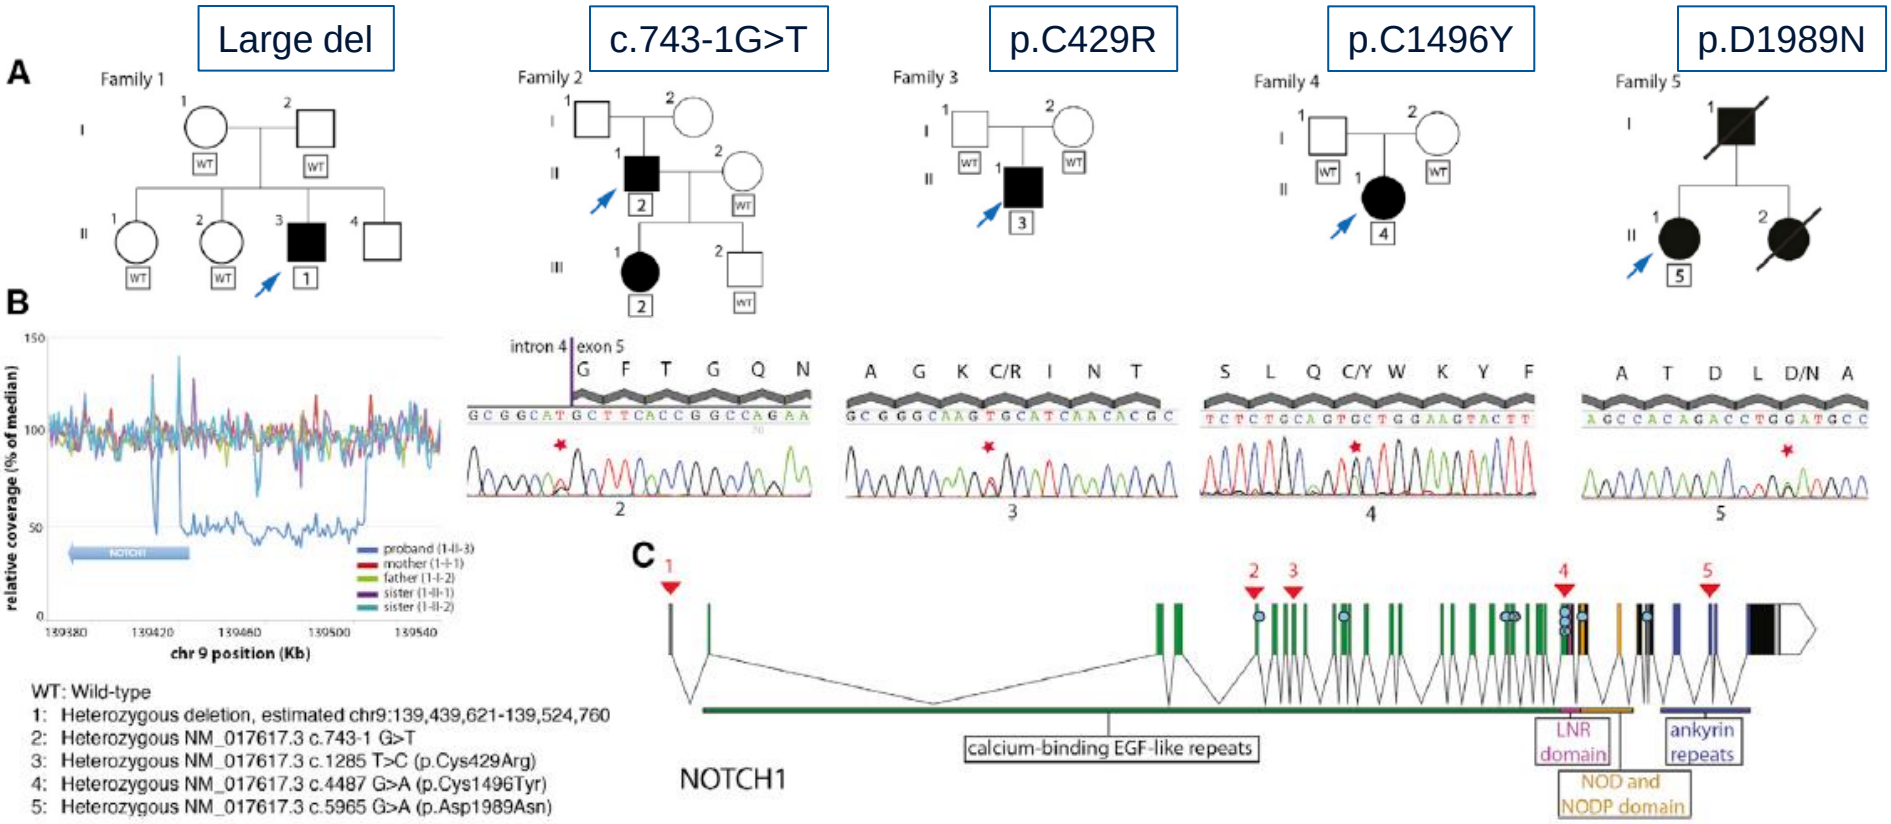
Cold Spring Harb Perspect Biol 2012;4:a011213

Loss of Function Mutations in *NOTCH1* cause Adams-Oliver Syndrome

REPORT

Mutations in *NOTCH1* Cause Adams-Oliver Syndrome

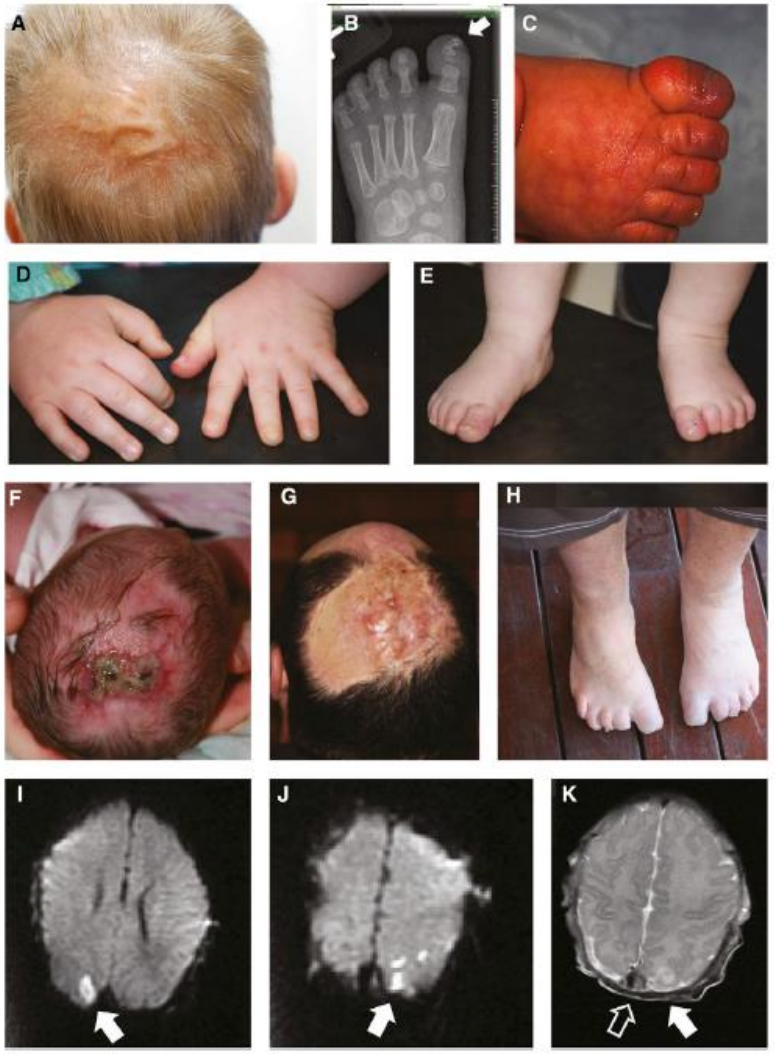
Anna-Barbara Stittrich,[1,9] Anna Lehman,[2,9] Dale L. Bodian,[3,9] Justin Ashworth,[1] Zheyuan Zong,[2]



WT: Wild-type
1: Heterozygous deletion, estimated chr9:139,439,621-139,524,760
2: Heterozygous NM_017617.3 c.743-1 G>T
3: Heterozygous NM_017617.3 c.1285 T>C (p.Cys429Arg)
4: Heterozygous NM_017617.3 c.4487 G>A (p.Cys1496Tyr)
5: Heterozygous NM_017617.3 c.5965 G>A (p.Asp1989Asn)

Am. J. Hum. Genet. 95: 275-284, 2014.

Characteristic Features of Adams-Oliver Syndrome



- Scarred aplasia curtis lesion of the scalp (Fig A, F, G)
- Calcific deposits in the subcutaneous tissue of first toe (Fig B) and terminal transverse defect of the toes and marmorata in infancy (Fig C, H)
- Distal hypoplasia of the digits of toes and hands (Fig D, E)
- Brain MRI showed infarcts and partial thrombus (Fig I, J, K)

Am. J. Hum. Genet. 95: 275-284, 2014.

Questions?

- Does the patient have Adams-Oliver? (No)
- Does the de novo mutation in *NOTCH1* cause patient's phenotype? (Don't know)
- Possible different disease-causing mechanism to cause a new syndrome? (Possible)

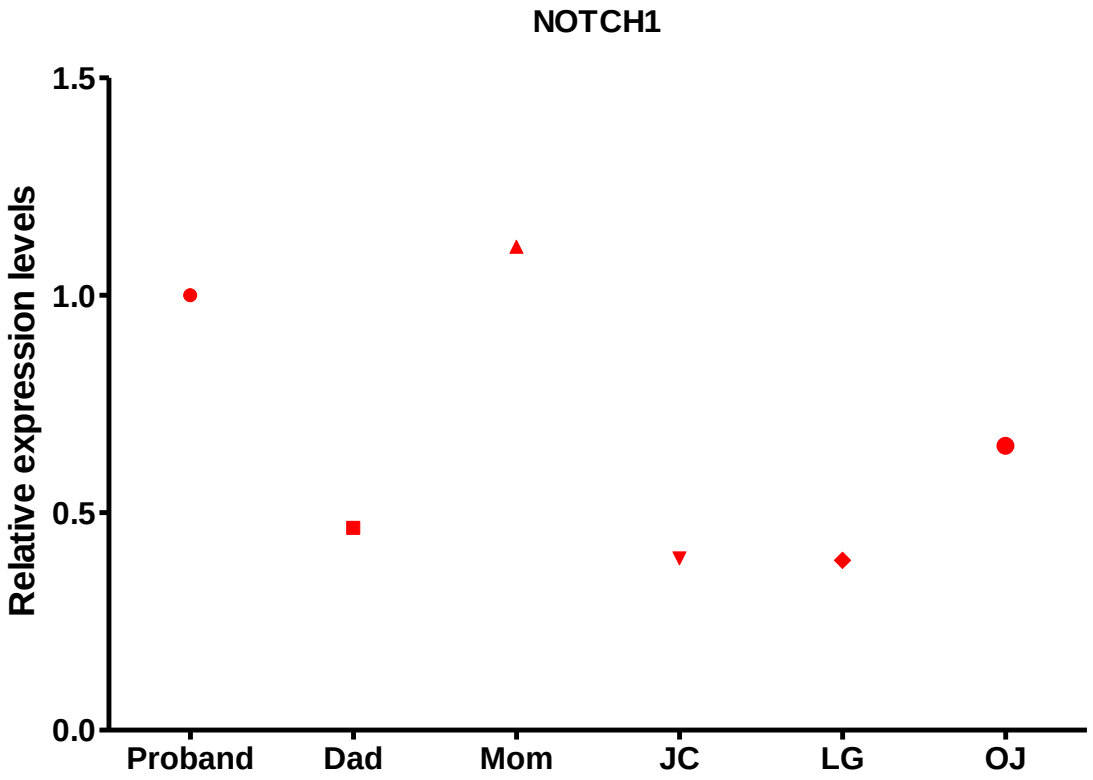
Next Step: Functional Study

- Mutagenesis and NOTCH1 gene expression.



Case 3: Re-analysis

Slides courtesy of Wei Shen, PhD

Clinical Information

- 8 yo Hispanic boy
- **Neurologic:** severe global DD, chorea, history of an intractable seizure disorder
- **Brain MRI:** mild bilateral perisylvian cortical dysplasia, nodular heterotopia
- **Dysmorphic features:** microcephaly, wide-spaced eyes, downturned corners of the mouth, U-shaped contour to the mouth with micrognathia
- **Skeletal:** hip dysplasia
- **EEG**: hypsarrhythmia
- **GI:** dysphagia, constipation
- **Growth parameters**: Wt 36%, Ht 22%, OFC 0%.
- **Surgeries:** device closure of PDA, repair of coronal hypospadias, bilateral tubes and revision
- **Previous normal testing**: karyotype and microarray, *TTP*, *CDKL5 MECP2*, *ARX* sequencing and del/dup, hearing test, purine panel, CDC transferrin, CSF studies (lactic acid, glucose, protein, amino acids), very long chain fatty acids,, mucopolysaccharides screen, lactic acid, plasma amino acids, acylcarnitine profile, urine organic acids, total carnitine, and lipid profile.
- **Family History:** maternal first cousin with seizures controlled by medication. Two maternal great aunts have severe intellectual disabilities and one is paralyzed from the waist down. No symptoms in mother.

- Proband ONLY

Negative Exome

- No strong candidate gene/variant identified
- Some variants to discuss

Gene	Transcript	Type	Zygosity	DNA alteration	Protein alteration	Inheritance mode	Human disease	Classification
CSTB	NM_000100	nonsense	het	c.C136T	p.Q46X	Autosomal recessive	Progressive myoclonic epilepsy 1A	Pathogenic
POLR3B	NM_018082	missense	het	c.G2158A	p.V720I	Autosomal recessive	Hypomyelinating leukodystrophy-8	VUS
GRID2	NM_001510	missense	het	c.A101G	p.D34G	Autosomal recessive	Spinocerebellar ataxia- 18	VUS
STARD9	NM_020759	missense	het	c.G986A	p.R329Q	Autosomal recessive	Okamoto et al (PMID 28777490)	VUS
	NM_020759	missense	het	c.C6955T	p.R2319W			VUS
TIMM17B	NM_001167947	missense	hemi	c.G304A	p.A102T	X-linked	Unknown	VUS

Compound Heterozygous Variants in STARD9

Gene	Transcript	Type	Zygosity	DNA alteration	Protein alteration	Inheritance mode	Human disease	Classification
STARD9	NM_020759	missense	het	c.G986A	p.R329Q	Autosomal recessive	Okamoto et al 2017 (PMID 28777490)	VUS
	NM_020759	missense	het	c.C6955T	p.R2319W			VUS

- *STARD9* gene encodes a protein that belongs to the kinesin-3 family. It associates with mitotic microtubules and regulates spindle pole assembly (Torres et al., 2011).

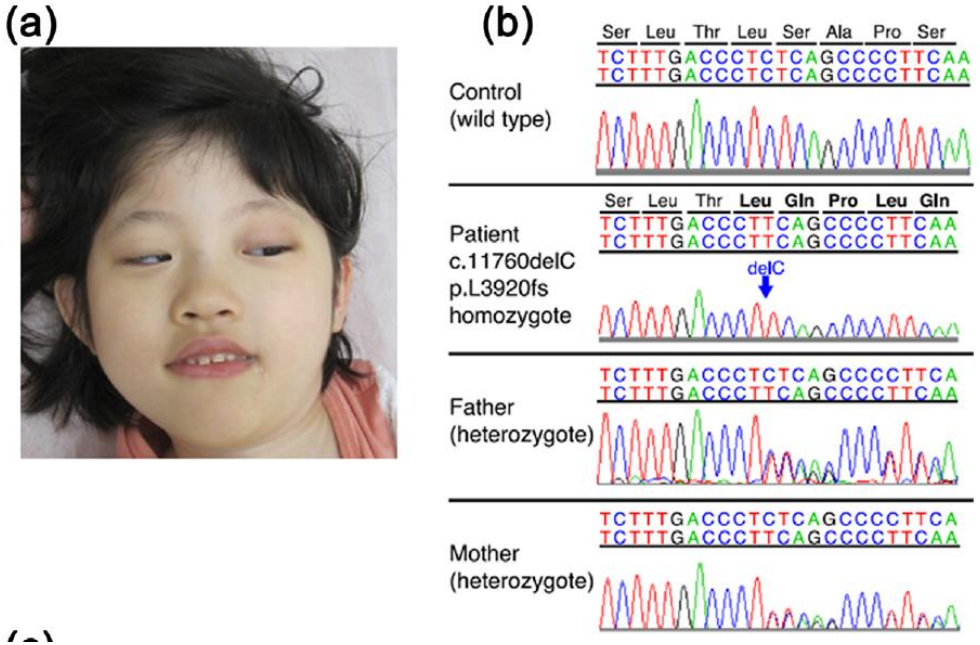
- Okamoto, et al., 2017 (PMID 28777490, Epub ahead of print on Aug 4, 2017) identified a homozygous pathogenic frame-shift variant in the *STARD9* gene via WES in one patient with severe intellectual disability, dysmorphic features, generalized tonic seizure, acquired microcephaly, cortical blindness, and sleep apnea.

ORIGINAL ARTICLE

WILEY American Journal of Medical Genetics Part A

A novel genetic syndrome with *STARD9* mutation and abnormal spindle morphology

Nobuhiko Okamoto[1,2] | Yuki Tsuchiya[3,4] | Fuyuki Miya[5,6] | Tatsuhiko Tsunoda[5,6] | Kumiko Yamashita[7] | Keith A. Boroevich[6] | Mitsuhiro Kato[8] | Shinji Saitoh[9] | Mami Yamasaki[10] | Yonehiro Kanemura[11,12] | Kenjiro Kosaki[13] | Daiju Kitagawa[3,4]



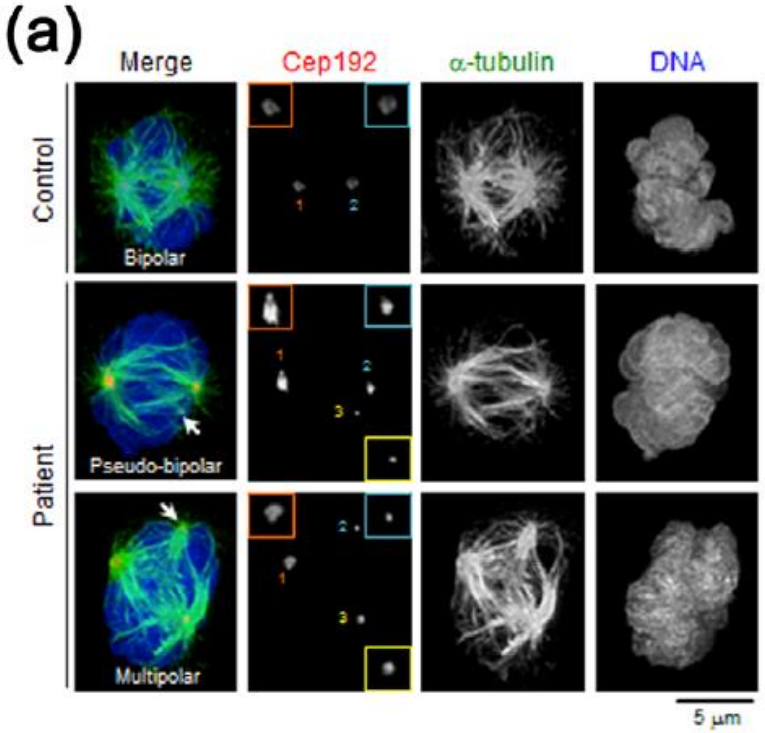
Clinical Report
6 yrs female

- **Neurologic**: Server DD, Seizure, less/no speech, cortical blindness, and sleep apnea
- **MRI**:
- **Dysmorphic features**: microcephaly, sparse eyebrow, epicanthal fold,
- **Muscle**: hypotonia, deep tendon reflexes were absent
- **Growth parameters**: height 99cm (-4.0SD), weight 11.7kg (-2.8SD), OFC47.0cm (-2.2SD)
- **GI**: poor feeding

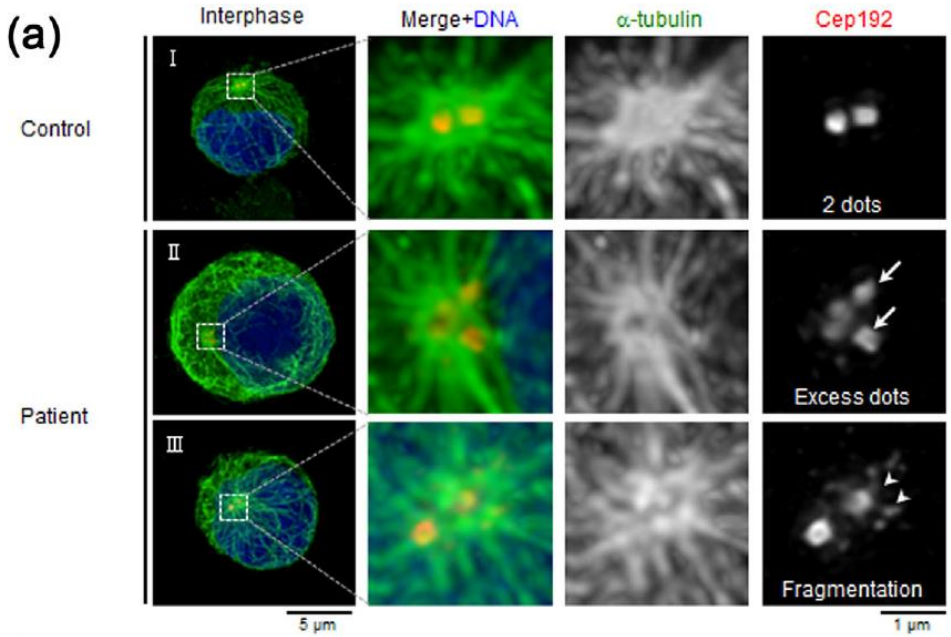
Mutation: homozygous of c.1176odelC, p.L3920fs in *STARD9*

Abnormal Spindle Morphology and Increase # of Centrosomes.

Abnormal spindle morphology



Increased number of centrosomes and fragmentation



Okamoto et al. 2017

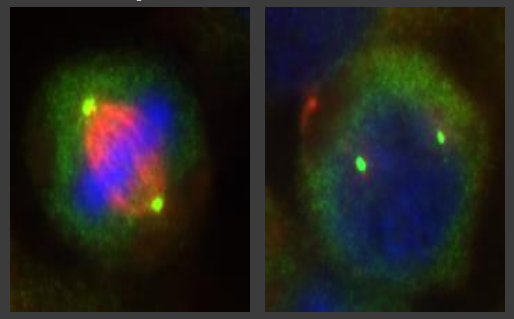
Research Collaboration with HCI

Dr. Katherine Ullman, Dollie LaJoie and Dr. Reha Toydemir

1) Initial antibody test on adherent HeLa cells (no smear gel) – CEP192 antibody works nicely

Metaphase Prometaphase

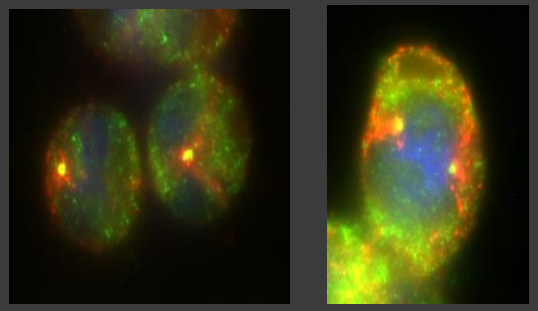
CEP192
Tubulin DNA



2) Optimized conditions using trypsinized HeLa cells (to mimic suspension cells) in smear gel:

Recently divided daughter cells Prometaphase

CEP192
Tubulin DNA

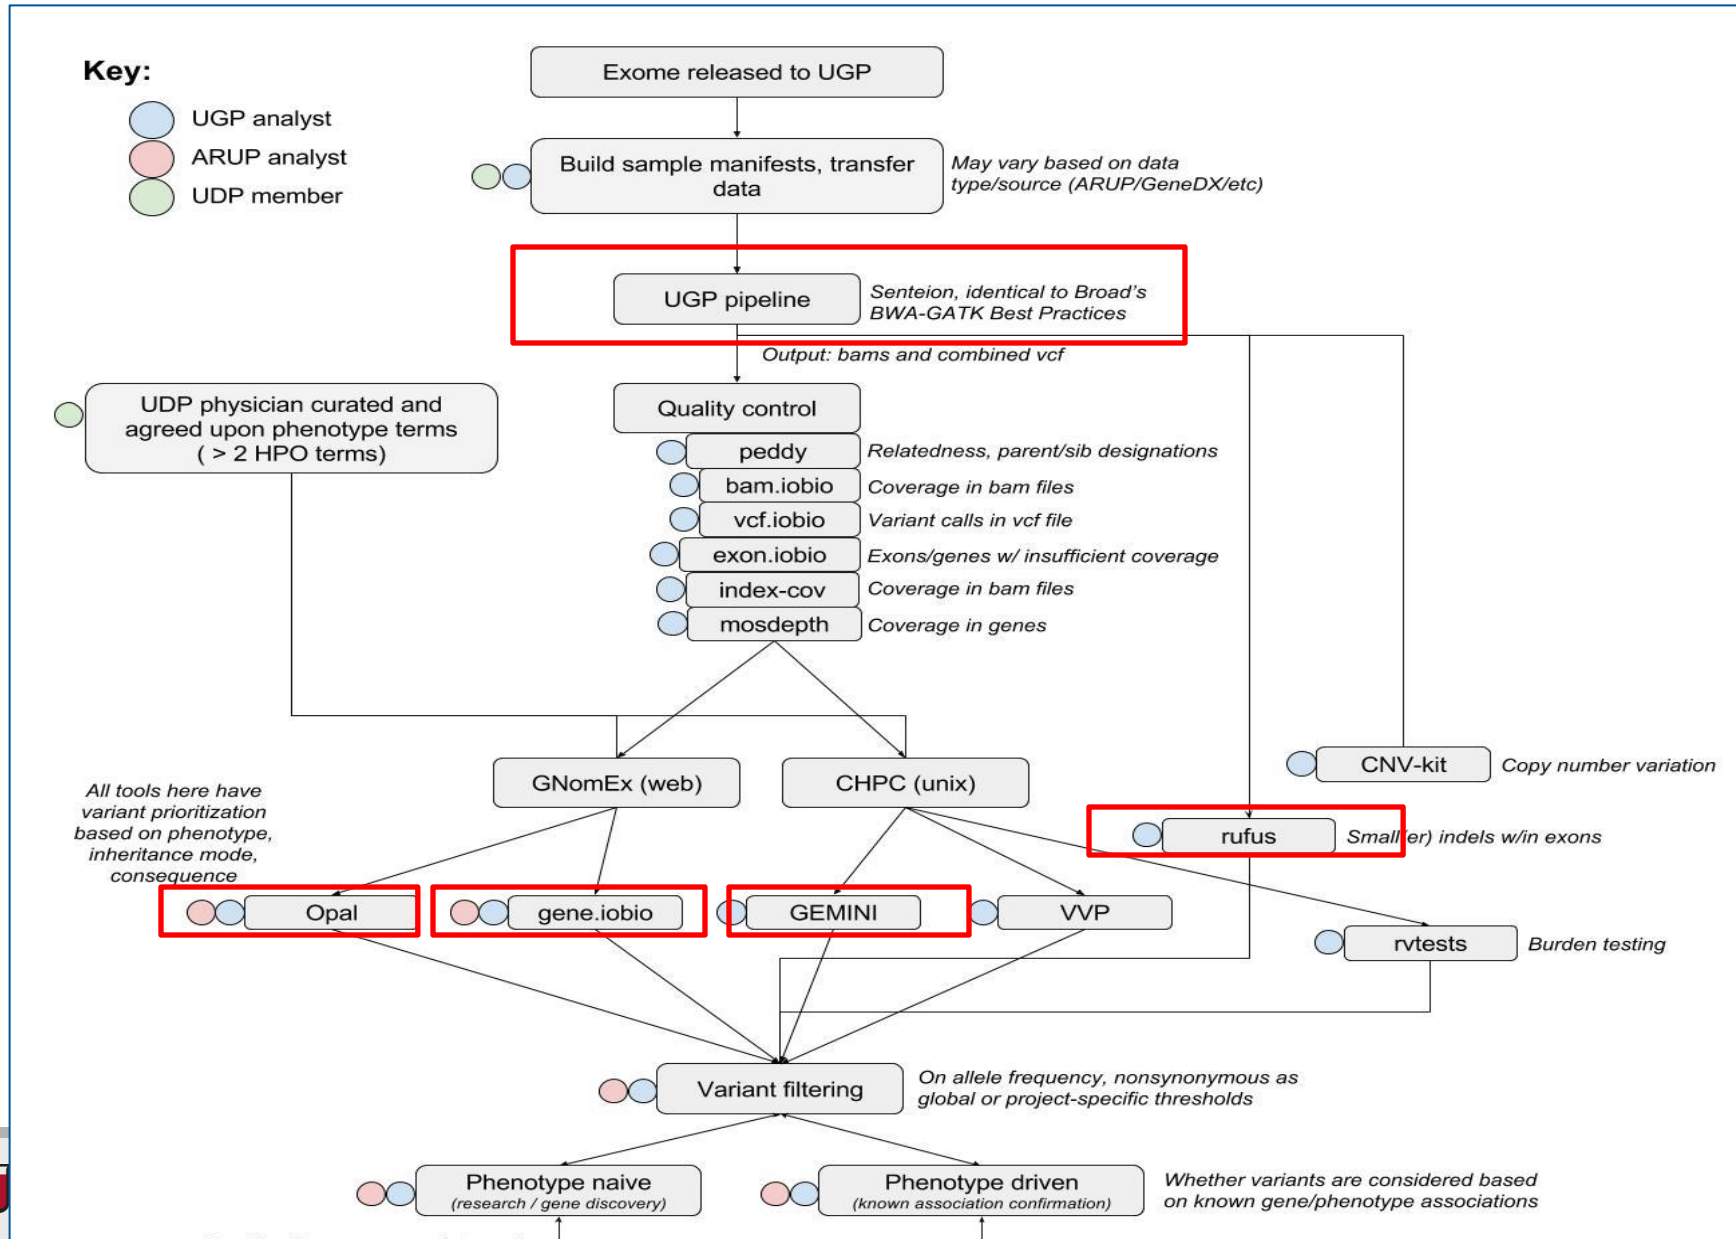


Re-analysis of Negative Exomes

- Re-analysis increased 10% of positive yield
- When to re-analysis exome? 6 months, one year or two years?
- Which bioinformatics pipeline to use?

Re-Analysis of Negative Exome Workflow

Collaboration with UGP, Drs. Gabor Marth and Matt Velinder



Summary

- Multidisciplinary team of UDP program developed a path to patient care: right patient, right diagnosis leading to right treatment
- It accomplished a goal to identify specific needs of rare disease clinic research: more collaboration, new gene discovery, exposure to patients and families and potential drug targets.
